

Hostplant Records and Natural History Notes on Costa Rican Butterflies (Papilionidae, Pieridae & Nymphalidae)

Philip J. DeVries

Department of Zoology, University of Texas, Austin, Texas 78712

Current address: Smithsonian Tropical Research Institute, Box 2072, Balboa, Panama

Abstract. Hostplant records for 209 species of butterflies in the families Papilionidae, Pieridae and Nymphalidae are reported from various habitats throughout Costa Rica to provide a basis for understanding fine-scale hostplant relationships of neotropical butterflies at the population level. Notes on egg, clutch-size, larval behavior, larval feeding, oviposition behavior, and hostplant microhabitat are given. New and unusual hostplant families and errors in the hostplant literature are discussed, and the possibilities of unrecognized sibling species masquerading under a single species name are indicated.

Introduction

To students of butterflies it has become evident that hostplant relationships play an increasingly important role in butterfly biology. Hostplant data have been used in developing classifications and systematics at the family, subfamily, genus, and species levels (Müller, 1886; Singer et al., 1983; DeVries et al., 1985), and in some cases the hostplant has been used as a character in naming populations (e.g. Murphy & Ehrlich, 1984). Hostplant data are of paramount importance for elucidating broad-scale evolutionary patterns of host use among systematic lineages (Brues, 1924; Ehrlich & Raven, 1965; Benson et al., 1976), for understanding butterfly ecology at the community (Gilbert, 1984) and population (Ehrlich, 1984) levels, for the dynamics of host-breadth and host shifts (Singer, 1983, 1984), and for the development of mimicry theory (Gilbert, 1983) and ecological chemistry (Brower, 1984). In short, hostplant relationships are a basis upon which we rest many of our ideas about butterflies.

Taken as a whole, it appears from surveys of literature records that hostplant relationships are well understood for the majority of the systematic lineages of butterflies (Ehrlich & Raven, 1965; P. Ackery, in prep.), particularly at higher systematic levels. However, this is not true with respect to specific butterfly faunas at the genus and species levels. Perhaps the only places on earth where such relationships are well known,

but not completely known at these levels are in the U.S.A., England, parts of northern Europe and Japan. In these areas fine-scale hostplant data are available for entire faunas which can be used to develop systematic and ecological studies with a critical degree of resolution. In all other areas of the world such data are not available, and this is especially so in the tropics. Although the tropics contain the greatest diversity of butterfly species, compared to temperate regions, hostplant relationships of butterflies are poorly known, and least known of all in the neotropics. If we are to gain an understanding of the butterflies of the neotropics comparable to our knowledge of the temperate regions, it is important to have a more complete picture of hostplant relationships than currently exists. This is a tall order considering that the neotropics contain a butterfly diversity greater than any other region on earth (DeVries, 1986). One very useful method is to develop hostplant lists for butterfly faunas of specific areas.

During a long term and continuing study of the butterfly fauna of Costa Rica I have had the opportunity to rear a number of species, as well as the good fortune to work with colleagues who, although involved in studies of their own, have provided me with hostplant records to augment my work. I here summarize the hostplant records for 209 species of Costa Rican butterflies in the families Papilionidae, Pieridae and Nymphalidae reared between 1976 and 1982 by my colleagues and myself. The purpose of this paper is to provide a starting point for eventually understanding fine-scale hostplant relationships at the population level for neotropical butterflies. Natural history information is provided for both butterflies and hostplants in coded form along with each hostplant record. In the remainder of this paper I highlight some new and unusual hostplant records, point to instances where there may be several species currently placed under one name, and draw attention to what I believe to be errors in previous literature. Additional hostplant records of Costa Rican butterflies and an analysis of the ecological patterns of hostplant use which are evident in the present paper will be discussed in a future publication (DeVries, in prep.).

Materials and Methods

Except where indicated, all hostplant records presented (Appendix I) have resulted from a larva feeding on a plant and developing into an adult. All records are from field collected eggs or larvae, except where otherwise noted. Oviposition records are indicated as such, the butterflies have been positively identified with a voucher specimen taken at the time of oviposition, or in a few cases, determined on the wing with the use of binoculars. Therefore, the vast majority of records reported here have voucher specimens in the collection of the author or the person responsible for the record.

Butterfly Nomenclature. The nomenclature follows DeVries (1986) which is modified and refined from DeVries (1983). Additional systematic references useful

for Costa Rican butterflies may be found in Ackery and Vane-Wright (1985), DeVries et al. (1985), Higgins (1981), Jenkins (1983) and Singer et al. (1983).

Plant Determinations. The hostplants in Appendix (I) are for the most part positively determined to genus (many to species), but in a few instances it was only possible to determine the plants to family due to undescribed taxa or insufficient plant material. The following people have lent their expertise in determining the hostplants: H. Bold, W. Burger, I. A. Chacon, R. Foster, L. D. Gomez, W. Haber, B. Hammil, L. Gilbert, G. Hartshorn, D. H. Janzen, S. Knapp, R. Marquis, R. Pohl, L. Poveda and F. G. Stiles. Useful references for identification of plants of Costa Rica include: Allen (1956), Burger (1971, 1977), Croat (1978), Daniels and Stiles (1979), Janzen and Leisner (1980) and Stiles (1980).

Coded Information in Appendix I: Explanations for the coded sequences in Appendix I are found in Tables I, II and III. This information is found in a series of columns located to the right of each butterfly taxon and corresponds to: hostplant identity, locality of record and who reared the butterfly, egg clutch-size, oviposition behavior, larval behavior, larval feeding and binomic notes concerned with the ovipositing butterfly and microhabit of the hostplant respectively. Further details on localities, habitats, and butterfly biology in Costa Rica are found in DeVries (1986).

All hostplant records reported here are from Costa Rica except those coded *AA and *KS. These come from Barro Colorado Island, Panama and augment Costa Rican records. Except for those hostplant records marked with an asterisk and a set of initials preceding the locality code, all records are those of DeVries. The initials refer to records of the following people: AA = A. Aiello, IC = I. A. Chacon, RC = R. Cubero, SK = S. Koptur, LEG = L. E. Gilbert, WH = W. Haber, DJ = D. H. Janzen, JM = J. Mallet, RM = R. Marquis, KS = K. Steiner, MCS = M. C. Singer, FGS = F. G. Stiles, and TR = T. Ray.

Comments

The hostplant records in Appendix I completely corroborate the pattern of relationship between hostplants and butterflies as described by Ehrlich and Raven (1965). There are, however, a few records in Appendix I which deserve special comment because they either represent hostplant families not reported in Ehrlich and Raven (1965), or they indicate a need for further study within the neotropical butterfly fauna as a whole. These records are briefly discussed here by butterfly family.

Papilionidae: The record of *Papilio cleotas* feeding on Moraceae requires confirmation since no papilionid species is known to feed on this plant family anywhere in the world. Hostplant records in the literature frequently report that *Papilio cresphontes* and *P. thoas* both utilize Rutaceae and Piperaceae as larval hostplants. Based on field experience and the data presented here I believe that such records are misidentifications of the butterfly species; the species are extremely similar in appearance. In Costa Rica *P. cresphontes* larvae feed only on Rutaceae,

and conversely, *P. thoas* larvae feed only on Piperaceae.

Pieridae: The records of *Catasticta* and *Pereute* feeding on Loranthaceae and the behavior and morphology of larvae and pupae suggest a close affinity to the extensive Old World genus *Delias*. The records also further amplify those reported in Ehrlich and Raven (1965). However, I believe the reference of *Pereute* feeding on the Lauraceae (Jörgensen, 1932) is in error (DeVries, 1982). I also believe the record of *Perrhybris lypera* feeding on Lauraceae is a plant misidentification (see Young, 1980, 1982; DeVries, 1982). The records of *Aphrissa statira* feeding on Bignoniaceae are very unusual for the Pieridae, and suggest either a chemical convergence between certain Bignoniaceae and Caesalpiniaceae or that there is more than a single species under the name *A. statira*.

Nymphalidae: The records of *Agrias amydon* on Erythroxylaceae represent an unusual hostplant family for the subfamily Charaxinae. It is further notable because of commercial interest in both the butterfly and chemistry of secondary chemicals of the hostplant genus. The record of *Zaretis itys* feeding on Piperaceae is unusual since its usual hostplants are Flacourtiaceae in the same habitat. Several interesting records are reported from the Nymphalinae. In my experience, the larvae of *Eunica monima* feed only on Burseraceae. I believe that the original record of this species feeding on Rutaceae (Dyar, 1912) represents a misidentification of the hostplant which subsequently became embedded in the literature. Muyshondt (1975) stated that Müller (1886) was in error for reporting *Diaethria marchalli* to feed on *Trema* (Ulmaceae) and said that in El Salvador he only found this species feeding upon Sapindaceae. In Costa Rica, *Trema* is the only hostplant for *D. marchalli* of which I am aware, suggesting that either the butterfly switches hostplant families in areas north of Costa Rica, or that there are two species of butterfly involved here. Data reported here suggest either that certain species of *Adelpha* are highly polyphagous, or that there are cryptic species involved under the same name (e.g. *A. boreas*, *A. celorio*, *A. heraclea*). *Adelpha melanthe*, on the other hand, changes hostplant family from east to west in Costa Rica, but all are closely allied within the Urticales. In the subfamily Satyrinae the record of *Megeuptychia antonoe* feeding on Cyclanthaceae is unusual, but Cyclanthaceae has recently been demonstrated to be a host of *Caligo* in Costa Rica as well (I. A. Chacon, pers. comm.). The record of *Euptychia insolata* feeding on Neckeraceae is the first record for any butterfly to utilize a member of the Bryophyta as a larval hostplant, although some members of the genus are known to feed on Lycopsida (Singer et al., 1983). Lastly, the records of *Pierella* and *Cissia confusa* on Poaceae, Marantaceae, Palmae and Heliconiaceae indicate a high degree of polyphagy, mostly within the same habitat.

Acknowledgments. I would first like to acknowledge a debt of gratitude to my

colleagues who were named previously, for allowing me to publish their hostplant records and who helped determine the hostplants. A special thanks to L. D. Gomez, D. H. Janzen, L. E. Gilbert and Servicios de Parques Nacionales de Costa Rica for logistical support. For babysitting caterpillars in the field during my absence and for assistance in the field I thank: I. A. Chacon, J. Denslow, A. Ehrlich, P. R. Ehrlich, L. E. Gilbert, W. Muriel Hallwachs, R. Hesterberg, D. H. Janzen, J. Longino, J. Mallet, R. Marquis, M. C. Singer, F. G. Stiles and C. Todzia. This manuscript benefited from comments by: P. R. Ackery, L. E. Gilbert, D. J. Harvey, D. H. Janzen, R. Marquis, R. Mattoni, C. D. Thomas and R. I. Vane-Wright. I dedicate this paper to the late A. Pepper. The publication of this paper was made possible from grants to the author made available from the Smithsonian Tropical Research Institute and the Dept. of Zoology, University of Texas.

LALT = Finca las Alturas (PUN)	

Costa Rican Province Codes are: (AL) = Alajuela, (CAR) = Cartago, (GUAN) = Guanacaste, (HER) = Heredia, (PUN) = Puntarenas, (SJ) = San José. The code (PAN) = the country Panamá.

Table 3. Codes Used for Eggs, Larvae and Hostplant in Appendix I.

Eggs and Oviposition

S = eggs laid singly

C = eggs laid in clusters

1 = female may oviposit several times on same plant.

2 = female usually oviposits only once on a plant.

3 = female always oviposits several times on same plant.

Larval Behavior

S = solitary

G = gregarious

1 = larvae feed on new, then old leaves.

2 = larvae will feed on all leaves.

3 = larvae feed only on young leaves.

4 = larvae feed only on older leaves.

5 = larvae feed on plant parts other than leaves.

Hostplant Microhabitat

1 = female oviposits on plants occurring in open areas.

2 = female oviposits on plants occurring in forest.

3 = female oviposits on plants occurring at forest or riparian edges.

4 = female oviposits on plants occurring in forest light gaps.

Appendix I. Reading from left to right the information in this appendix is divided into five columns corresponding to: 1) butterfly taxa, 2) hostplant, locality and authorships of rearing, 3) clutch-size of eggs and frequency of oviposition, 4) larval behavior and feeding and 5) micro-habitat of hostplant and natural history notes. Explanations for the coded sequences are found in the text and in Tables 1, 2 and 3.
